

## SUBSTITUTE ABSTRACT

A pasta cooker has a base carrying a bowl having an electrical heater. A basket can move between a lower position immersed in water in the bowl and an upper position largely out of the bowl. A stirring element rotatably mounted on the basket carries a paddle projecting upward into the basket. A controller energizes the heater to bring the water in the bowl to a boil, then lowers the basket into it. The stirring element fits with a drive in the base so it can rotate and stir the water and any foodstuff in the bowl in the boiling water. After an interval preset in a timer elapses, the controller lifts the basket out of the bowl.
